

Audited objects

per-pixel σ and $|e|$
4 released
mechanisms, 2
backbones

Severity strata

input-only proxy:
grayscale contrast,
quartiles
S1 (heaviest)
to S4 (lightest)

Three metric families

Coverage (magnitude):
is $|e| \leq \sigma$ as often as claimed?
Ranking (order): are the high- σ
pixels the erring ones?
Utility: error removed at retention

Two operations

Recalibrate: one
scalar r from ~ 100 refs
Reject: drop the
most-uncertain pixels

Deployment rule: recalibrate per water body, trust rejection only to ensembles, never select by marginal coverage
